Model Checking Based Test Generation
from P Systems Using P-Lingua

Abstract. This paper presents an approach for P system testing, that uses model-checking for automatic test generation and P-Lingua as specification language. This approach is based on a transformation of the transitional, non-deterministic, cell-like P system into a Kripke structure, which is further used for test generation, by adding convenient temporal logic specifications. This paper extends our previous work in this field to multi-membrane, transitional P system, having cooperative rules, communication between membranes and membrane dissolution. A tool, which takes as input a P system specified in P-Lingua and translates it into the language accepted by the model checker NuSMV has been developed and used for test case generation. Some hints regarding the automatic test generation using NuSMV and P-Lingua are also given.

1. Introduction

Membrane computing is a branch of natural computing, which investigates parallel computing models, inspired by the structure of the living cell, called *P systems*. These computational models, were introduced by Gheorghe Păun in 1998, in its seminal research report, further published as journal paper [18]. Membrane computing has known a fast growth in the last years: many variants of P systems have been proposed and results concerning their computational power and universality have been obtained. A recent handbook summarizes the most important developments in this field [20]. For all these P system variants, different implementations and simulators have been developed and consequently it appears the necessity of testing these implementations.

A first approach on testing P systems focuses on cell-like models and proposes some coverage criteria [11], which are empirically evaluated in [15]. Automatic test generation for P systems using model-checking is proposed in [14].

Given a model of a system, *model checking* [6] is a formal verification technique that explores the entire state space and decides whether this model meets a given property, expressed in temporal logic. If the property does not hold, then a counterexample is returned. This capability of model checkers to construct counterexamples provides a way to build test sets. Fraser et al. present in a recent and comprehensive survey [9] the results obtained over the last decade in software testing using model checkers.

One of the approaches used to obtain a test suite using model checking follows the steps [9]:

1. A *test purpose* is defined, describing the expected features of the test case, for example: reaching a certain state s in the model, covering a transition t, traversing a sequence of states, getting a certain value val of a variable x, etc.

2. These features are further specified as temporal logic properties and then converted by negation into *never-claim* conditions, or *trap properties*, such as: `G !(state = s)`, expressing that the system will never reach state s, or `G !(x = val)`, expressing that the value val is never taken (x is always different from val).

3. The model checker will verify whether the *never-claim* or *trap property* holds. If the property is false, it returns a counterexample that gives the exact path in the model which satisfies the test purpose, e.g., reaches state s or sets the system variable x to val. The counterexample will provide all the information needed to extract the test case. If the property is true, then it is impossible to build a test case satisfying the given purpose.

Regarding P system testing, one intuitive test criterion is *rule coverage*, that specifies that the test set should contain test cases which cover every rule, i.e., for each rule there exists a test case, describing a computation which involves that rule. More powerful test sets can be computed by considering the *context-dependent rule coverage* criterion. This considers coverage of rules in the context defined by other rules.

An approach on building test cases for P systems using model checking was proposed in [14]. It transforms the P system specification into a Kripke structure, then properties regarding the coverage criteria are expressed in LTL (Linear Temporal Logic) and added to the NuSMV specification. This paper extends the work from [14] in the following aspects:

- It employs the P-Lingua framework [10], to specify the P system and verify its syntactic correctness.

- It uses multi-membrane P systems, having cooperative and communication rules between membranes (the approach presented in [14] treats only one-membrane P systems, with cooperative rules).

- A transformation of P systems with *membrane dissolution* into the SMV (Symbolic Model Verifier) language is proposed.

- *Bounded model checking* (BMC) is used to obtain the shortest counterexamples. This is useful in practice, to obtain a reduced test suite.

- The paper shows how other properties can be verified against the transformed model, to find possible faults in the P system.

2. Background

In the rest of the paper, we will use the following notations: V^* for the set of all strings over the alphabet $V = \{a_1, ..., a_p\}$ and λ to denote the empty string. For a string $u \in V^*$, $|u|_{a_i}$ denotes the number of a_i occurrences in u. Each string u has an associated vector of non-negative integers: $\Psi_V : V^* \to N^p$, $\Psi_V(u) = (|u|_{a_1}, ..., |u|_{a_p})$.

2.1. P systems

A basic cell-like P system is defined as a hierarchical arrangement of membranes identifying corresponding regions of the system. Each region has associated a finite multiset of objects and a finite set of rules; both may be empty. A multiset is either denoted by a string $u \in V^*$, where the order is not considered, or by $\Psi_V(u)$. The following definition refers to one of the many variants of P systems, namely cell-like P systems, which use transformation and communication rules [19]. We will call these processing rules. Since now onwards we will call this model P system.

Definition 2.1. A *P system* is a tuple $\Pi = (V, \mu, w_1, ..., w_n, R_1, ..., R_n)$, where V is a finite set, called *alphabet*; μ defines the membrane structure, which is a hierarchical arrangement of n compartments called *regions* delimited by *membranes* - these membranes and regions are identified by integers 1 to n; w_i, $1 \le i \le n$, represents the initial multiset occurring in region i; R_i, $1 \le i \le n$, denotes the set of processing rules applied in region i.

The membrane structure, μ, is a tree like structure represented by a string of left and right brackets ($[_i$, and $]_i$), each with the label of the membrane i, it points to; μ also describes the position of each membrane in the hierarchy. The rules in each region have the form $u \to (a_1, t_1)...(a_m, t_m)$, where $u \in V^+$ is a multiset of symbols from V, $a_i \in V$, $t_i \in \{in, out, here\}$, $1 \le i \le m$. When such a rule is applied to a multiset u in the current region, u is replaced by the symbols a_i with $t_i = here$; symbols a_i with $t_i = out$ are sent to the outer region or outside the system when the current region is the external compartment and symbols a_i with $t_i = in$ are sent into one of the regions contained in the current one, arbitrarily chosen. In the following definitions and examples when the target indication is *here*, the pair $(a_i, here)$ will be replaced by a_i. The rules are applied in maximally parallel mode.

A configuration of the P system Π, is a tuple $c = (u_1, ..., u_n)$, where $u_i \in V^*$, is the multiset associated with region i, $1 \le i \le n$. A computation from a configuration

c_1 to c_2 using the maximal parallelism mode is denoted by $c_1 \implies c_2$. In the set of all configurations we will distinguish terminal configurations; $c = (u_1, ..., u_n)$ is a *terminal configuration* if there is no region i such that u_i can be further developed.

We say that a rule is *cooperative* if it has at least two objects in its left hand side, e.g., $ab \rightarrow (c, in)(d, out)$. Otherwise, the rule is *non-cooperative*, e.g., $a \rightarrow (c, in)(d, out)$. The rules can also have the form $u \rightarrow v\delta$, where δ denotes the action of *membrane dissolution*: if the rule is applied, then the corresponding membrane disappears and its contents, object and membranes alike, are left free in the surrounding membrane; the rules of the dissolved membrane disappear with the membrane. The skin membrane is never dissolved. For further details regarding membrane computing, please refer to [19].

2.2. P-Lingua

P-Lingua is a programming language for membrane computing [8], developed by members of the Research Group on Natural Computing, at the University of Seville. It is developed as a free software framework for cell-like P systems and can be downloaded from http://www.p-lingua.org. Its main component is a Java library, `pLinguaCore`, that accepts as input text files (either in XML or in P-Lingua format) describing the P system model [10].

The library includes several built-in simulators for each supported model. P-Lingua 2.0 was designed for cell-like P systems and contains simulators for the following types of P systems: active membrane with division/creations rules, transition, symport/antiport, stochastic and probabilistic P systems. P-Lingua 2.1 (actual version) was extended for tissue P systems with symport/antiport rules and cell division [16].

The P-Lingua software package contains the `pLinguaCore` library and a user interface called `pLinguaPlugin`. It was used in several research papers, e.g., to solve a SAT problem using a family of P systems [8], to describe and simulate ecosystems by means of P systems [10].

2.3. Kripke structures

Definition 2.2. *A Kripke structure* over a set of atomic propositions AP is a four tuple $M = (S, H, I, L)$, where S is a finite set of states; $I \subseteq S$ is a set of initial states; $H \subseteq S \times S$ is a transition relation that must be left-total, that is, for every state $s \in S$ there is a state $s' \in S$ such that $(s, s') \in H$; $L : S \longrightarrow 2^{AP}$ is an interpretation function, that labels each state with the set of atomic propositions true in that state.

Usually, the Kripke structure representation of a system results by giving values to every variable in each configuration of the system. Suppose $var_1, \ldots, var_n$ are the system variables, Val_i denotes the set of values for var_i and val_i is a value from Val_i, $1 \leq i \leq n$. Then the states of the system are $S = \{(val_1, \ldots, val_n) \mid val_1 \in Val_1, \ldots, val_n \in Val_n\}$, and the set of atomic predicates are $AP = \{(var_i = val_i) \mid 1 \leq i \leq n, val_i \in Val_i\}$. Naturally, L will map each state (given by the values of

variables) onto the corresponding set of atomic propositions. For convenience, in the sequel the expressions of AP and L will not be explicitly given, the implication being that they are defined as above.

2.4. NuSMV

NuSMV is a symbolic model checker [3], developed as part of a joint project between Carnegie Mellon University and Istituto per la Ricerca Scientifica e Tecnologica. NuSMV is the result of the reengineering, reimplementation, and, to a limited extent, extension of the SMV model checker [17]. It is publicly available at http://nusmv.irst.itc.it/. NuSMV [3] can process files written in SMV (Symbolic Model Verifier) language [17]. The NuSMV language is mostly source compatible with the original version of SMV and it supports LTL (*Linear Temporal Logic* [21] and CTL (*Computation Tree Logic*) [5] as temporal specification logics.

The input language of NuSMV was designed to allow descriptions of Finite State Machines (FSMs), more precisely to describe the transition relation of the FSM. For example, considering a finite state machine with three states, $\{running, halt, crash\}$ the transition relation of the FSM can be expressed also using the TRANS keyword as follows:

```
MODULE main
VAR
  state : {running, halt, crash};
ASSIGN
  init(state) := running;
TRANS
  state = running & next(state) = running |
  state = running & next(state) = halt |
  state = running & next(state) = crash |
  state = halt & next(state) = halt |
  state = crash & next(state) = crash
```

Having a model described in NuSMV, one can add LTL or CTL specifications to be verified by the model checker. In LTL path properties can be expressed, having atomic propositions as state subformulas. For example, if f and g are path formulas, then $\neg f$, $f \vee g$, $f \wedge g$, $\mathbf{X}f$, $\mathbf{F}f$, $\mathbf{G}f$ are path formulas, where: the $\mathbf{X}$ operator ("neXt time") requires that a property holds in the next state of the path; the $\mathbf{F}$ operator ("eventually" or "in the future") is used to assert that a property will hold at some state on the path and $\mathbf{G}$ ("always" or "globally") specifies that a property holds at every state on the path. A complete list of LTL operators, can be found in [6].

For the previous model, the specification LTLSPEC G !(F state = halt) is false and the counterexample obtained is the path: $running \rightarrow halt \rightarrow halt \rightarrow \ldots$ (the system will eventually remain in the *halt* state). On the other hand, the specification LTLSPEC G !(state = halt & X state = running) is true (there is no transition from the *halt* state, having the next state *running*).

3. Coverage criteria for P systems

A set of coverage criteria for P system rules, inspired from grammar testing, is presented in [11]. Test sets should be further designed to satisfy each coverage criterion. In the following we summarize the main coverage criteria, but for simplicity, we will provide the definitions only for one membrane P systems, $\Pi = (V, \mu, w, R)$, $\mu = [_1]_1$.

Definition 3.1. A multiset denoted by $u \in V^*$, *covers* a rule $r : a \to v \in R$, if there is a computation $w \Longrightarrow^* xay \Longrightarrow x'vy' \Longrightarrow^* u$; $x, y, x', y', v, u \in V^*$, $a \in V$, $w \in V^*$ is the initial multiset. If there is no further computation from u, then this is called a *terminal coverage*.

Definition 3.2. A set $T \subseteq V^*$, is called a *test set* that satisfies the *rule coverage* (RC) criterion if for each rule $r \in R$ there is $u \in T$ which covers r. If every $u \in T$ provides a terminal coverage then T is called a test set that satisfies the *rule terminal coverage* (RTC) criterion.

Definition 3.3. A rule $r \in R$, $r : a \to ubv$, $u, v \in V^*$, $a, b \in V$, is called a *direct occurrence* of b. For every symbol $b \in V$, we denote by $Occs(\Pi, b)$, the set of all direct occurrences of b.

Definition 3.4. A multiset $z \in V^*$ *covers* the rule $r : b \to y \in R$ for the *direct occurrence* of b, $a \to ubv \in R$, if there is a computation $w \Longrightarrow^* u_1 a v_1 \Longrightarrow u_1' ubv v_1'$ $\Longrightarrow u_1'' u' y v' v_1'' \Longrightarrow^* z$; $u, v, u', v', u_1, v_1, u_1', v_1', u_1'', v_1'', y \in V^*$, $a, b \in V$. A set T_r is said to cover $r : b \to y$ for all direct occurrences of b if for any occurrence $o \in Occs(\Pi, b)$ there is $t \in T_r$ such that t covers r for o.

Definition 3.5. A set T is said to achieve *context-dependent rule coverage* (CDRC) for Π if it covers all $r \in R$ for all their direct occurrences. If every $z \in T$ provides a terminal coverage then T is called a test set that satisfies the *context-dependent rule terminal coverage* (CDRTC) criterion.

To illustrate these concepts, we consider the P system $\Pi = (V, \mu, w, R)$ where: $V = \{a, b, c\}$, $\mu = [_1]_1$, $w = a$, $R = \{r_1 : a \to bc; r_2 : b \to bc; r_3 : b \to c\}$. It can be verified that the set $T = \{c^3\}$ covers all the rules, because the computation $a \Longrightarrow bc \Longrightarrow bc^2 \Longrightarrow c^3$ applies the rules r_1, r_2, r_3. Note that c^3 is a terminal configuration and, consequently, $T = \{c^3\}$ satisfies the RTC criterion. The test set $T' = \{bc^2, c^2\}$ achieves the CDRC criterion, because it covers the rules r_2, r_3, each one in the context defined by r_1. A test set satisfying the CDRTC is $T'' = \{c^2, c^3\}$.

4. Transforming a one-membrane P system into a Kripke structure

In a previous paper [14], a transformation of a one-membrane P system into a Kripke structure was proposed and several theoretical aspects were analysed. To simplify the presentation, we will consider here only one-membrane P systems and

show in next section how this approach can be extended to a multi-membrane system. We assume that the universal clock governs the computation of the P system.

Consider the one-membrane P system $\Pi = (V, \mu, w, R)$, where $R = \{r_1, \ldots, r_m\}$; each rule r_i, $1 \leq i \leq m$, is of the form $u_i \longrightarrow v_i$, where u_i and v_i are multisets over the alphabet V. In the sequel, we treat the multisets as vectors of non-negative integers, that is each multiset u is replaced by $\Psi_V(u) \in \mathbf{N}^k$, where k denotes the number of symbols in V; so, we will write $u \in \mathbf{N}^k$.

In order to define the Kripke structure associated to Π we use two predicates *MaxPar* and *Apply* (similar to [7]): $MaxPar(u, u_1, v_1, n_1, \ldots, u_m, v_m, n_m)$, $u \in \mathbf{N}^k$, $n_1, \ldots, n_m \in \mathbf{N}$ signifies that a computation from the configuration u in maximally parallel mode is obtained by applying rules $r_1 : u_1 \longrightarrow v_1, \ldots, r_m : u_m \longrightarrow v_m$, $n_1, \ldots, n_m$ times, respectively (in particular, $MaxPar(u, u_1, v_1, 0, \ldots, u_m, v_m, 0)$ signifies that no rule can be applied and so u is a terminal configuration); $Apply(u, v, u_1, v_1, n_1, \ldots, u_m, v_m, n_m)$, $u, v \in \mathbf{N}^k$, $n_1, \ldots, n_m \in \mathbf{N}$, denotes that v is obtained from u by applying rules $r_1, \ldots, r_m$, $n_1, \ldots, n_m$ times, respectively.

In order to keep the number of configurations finite, for each configuration $u = (u^{(1)}, ..., u^{(k)})$ we will assume that each component, $u^{(i)}$, $1 \leq i \leq k$ cannot exceed an established upper bound, denoted Max, and each rule can only be applied for at most a given number of times, denoted Sup. Naturally, by keeping the number of states finite, we also avoid decidability issues normally associated with P system model checking [7].

We denote $u \leq Max$ if $u^{(i)} \leq Max$ for every $1 \leq i \leq k$ and $(n_1, \ldots, n_m) \leq Sup$ if $n_i \leq Sup$ for every $1 \leq i \leq m$; $\mathbf{N}^k_{Max} = \{u \in \mathbf{N}^k \mid u \leq Max\}$, $\mathbf{N}^m_{Sup} = \{(n_1, \ldots, n_m) \in \mathbf{N}^m \mid (n_1, \ldots, n_m) \leq Sup\}$. Analogously to [7], the system is assumed to crash whenever $u \leq Max$ or $(n_1, \ldots, n_m) \leq Sup$ does not hold (this is different from the normal termination, which occurs when $u \leq Max$, $(n_1, \ldots, n_m) \leq Sup$ and no rule can be applied). Under these conditions, the one-membrane P system Π can be described by a Kripke structure $M = (S, H, I, L)$ with $S = \mathbf{N}^k_{Max} \cup \{Halt, Crash\}$ with $Halt, Crash \notin \mathbf{N}^k_{Max}$, $Halt \neq Crash$; $I = w$ and H defined by:

- $(u, v) \in H$, $u, v \in \mathbf{N}^k_{Max}$, if $\exists (n_1, \ldots, n_m) \in \mathbf{N}^m_{Sup} \setminus \{(0, \ldots, 0)\}$ · $MaxPar(u, u_1, v_1, n_1, \ldots, u_m, v_m, n_m) \wedge$ $Apply(u, v, u_1, v_1, n_1, \ldots, u_m, v_m, n_m)$;

- $(u, Halt) \in H$, $u \in \mathbf{N}^k_{Max}$, if $MaxPar(u, u_1, v_1, 0, \ldots, u_m, v_m, 0)$;

- $(u, Crash) \in H$, $u \in \mathbf{N}^k_{Max}$, if $\exists (n_1, \ldots, n_m) \in \mathbf{N}^m, v \in \mathbf{N}^k$ · $\neg((n_1, \ldots, n_m) \leq Sup \wedge v \leq Max) \wedge MaxPar(u, u_1, v_1, n_1, \ldots, u_m, v_m, n_m) \wedge$ $Apply(u, v, u_1, v_1, n_1, \ldots, u_m, v_m, n_m)$;

- $(Halt, Halt) \in H$;

- $(Crash, Crash) \in H$.

It can be observed that the relation H is left-total.

The main result of [14] can be summarized by the following theorem:

Theorem 4.1. *Given an one-membrane P system* $\Pi = (V, [_1]_1, w_1, R)$, *(terminal) test suites satisfying the rule coverage and context dependent rule coverage criteria are generated based on LTL specifications.*

This means that having the transformation into a Kripke structure, what we need is to verify the following LTL specifications:

- $G\neg((n_i \geq 1) \wedge (state = other))$, for each rule $r_i \in R$, in order to achieve rule coverage (RC).

- $G\neg((n_i \geq 1) \wedge (state = other) \wedge F(state = halt))$, for each rule $r_i \in R$, in order to obtain rule terminal coverage (RTC).

- $G\neg((n_i \geq 1) \wedge X((n_j \geq 1) \wedge (state = other)))$, for each pair of rules $(r_i, r_j) \in R \times R$, where r_j can be applied the context of r_i, in order to achieve context dependent rule coverage (CDRC).

- $G\neg((n_i \geq 1) \wedge X((n_j \geq 1) \wedge (state = other)) \wedge F(state = halt))$, for each pair of rules $(r_i, r_j) \in R \times R$, where r_j can be applied the context of r_i, in order to obtain context dependent rule terminal coverage (CDRTC).

5. Generating the test suits

5.1. The test generation tool

Following the test generation strategy presented previously, a tool has been developed. A graphical interface allows editing and verification of PLI files, representing the specification of P systems in P-Lingua. The tool communicates with the P-Lingua framework, using its parser to syntactically verify the specification. Once the specification contains no syntactically errors, the corresponding objects from the library `pLinguaCore` are created. For a given `Psystem` object, an SMV file is created, containing the associated SMV model (corresponding to the Kripke structure). The user has the possibility to choose which of the following coverage criteria should be employed: RC, RTC, CDRC, CDRTC. For each coverage criteria LTL specifications, representing never-claim formulas, are added to the SMV file. Finally, the NuSMV model checker is run against the model specified in SMV, the counterexamples are decoded and transformed into test cases.

Having a P system specified in P-Lingua, the tool automatically transforms it into a SMV model. This model depends on the type of P system and in the following subsections we will present the transformation strategies proposed for different types of P systems. After the transformations the LTL specifications are automatically generated and appended to the SMV file. More details regarding the tool and some examples can be found at the following web page: http://fmi.upit.ro/evomt/psys/psys_tools.html.

5.2. Transforming one-membrane P systems into SMV

For an one-membrane P system $\Pi = (V, \mu, w, R)$, with $V = \{a_1, \ldots, a_k\}$ and $R = \{r_1, \ldots r_m\}$ (each rule r_i has the form $u_i \longrightarrow v_i$), its associated Kripke structure is $M = (S, H, I, L)$. The state space of M is implemented by using a 3-valued "state" variable (with values "Halt", "Crash" and "Running") and appropriate variables to hold the current configuration and the number of applications of each rule. Therefore, the NuSMV model will contain:

- k variables, labelled exactly like the objects from the alphabet V, each one showing the number of occurrences of each object, $a_i \in V$, $1 \leq i \leq k$;

- m variables n_i, $1 \leq i \leq m$, each one showing the number of applications of $r_i \in R$, $1 \leq i \leq m$;

- one variable *state* showing the current state of the model, $state \in \{Running, Halt, Crash\}$;

- two constants, Max corresponding to the upper bound for the number of occurrences expressed by each $a_i \in V, 1 \leq i \leq k$ and Sup which shows that each rule $r_i, 1 \leq i \leq m$, can be applied at most Sup times (see Section **??**).

With these notations we are prepared to construct a NuSMV specification as a FSM where the states and transitions are defined below and also abstracted in the model from section 2.4.

If the current state is $Running$ then this is characterized by the values provided by $a_1 \geq 0, \ldots, a_k \geq 0$; the maximal parallelism condition will be written as a conjunction $c_1 \wedge \cdots \wedge c_m$, where each condition c_i, $1 \leq i \leq m$, corresponds to rule r_i and is a disjunction $c_i = c_{i_1} \vee \cdots \vee c_{i_p}$, given that the left hand side of r_i is $a_{i_1}^{t_{i_1}} \ldots a_{i_p}^{t_{i_p}}$. The condition c_{i_j}, $1 \leq j \leq p$, is $0 \leq a_{i_j} - n_1 h_1 - \cdots - n_m h_m < t_{i_j}$, where $n_1, \ldots, n_m$ represent the values provided by $MaxPar$ and $h_q \geq 0$ represents the number of occurrences of symbol a_{i_j} on the left hand side of r_q, $1 \leq q \leq m$. This condition simply states that, after applying all rules in a maximal parallel way, the number of occurrences of symbol a_{i_j} left is less than the number of occurrences of a_{i_j} appearing on the left hand side of r_i, i.e., this rule can no longer be applied for this step. When the number of occurrences of the symbol a_{i_j} in the left side of a rule r_q is equal to 1, then the above inequality $0 \leq a_{i_j} - n_1 h_1 - \cdots - n_m h_m < t_{i_j}$ becomes $0 = a_{i_j} - n_1 h_1 - \cdots - n_m h_m$ (because $t_{i_j} = 1$).

The values $a_1 \geq 0, \ldots, a_k \geq 0$ that characterize the next state are computed as follows. Using the above notations and denoting by $next(a)$ the new value, we have $next(a_{i_j}) = a_{i_j} - n_1 h_1 - \cdots - n_m h_m + n_1 h_1' + \cdots + n_m h_m'$, where $h_q' \geq 0$ represents the number of occurrences of symbol a_{i_j} on the right hand side of r_q.

Some additional conditions are added to the above ones in order to distinguish the destination state. These are obvious and derive from the upper bound conditions introduced. The example below illustrates the approach. We notice that all these conditions and the entire NuSMV specification, including the LTL expressions, are

automatically derived from a P system using the tool developed by the authors of this paper.

We illustrate the approach by using a nondeterministic P system, which models the predator-prey problem: $\Pi_1 = (V_1, \mu, w_1, R_1)$, having $V_1 = \{a, b, x, y\}$, $\mu = [_1]_1$, $w_1 \in V^+$, $R_1 = \{r_1 : a \to a^2 : r_2 : ax \to x^2; r_3 : xy \to y^2; r_4 : y \to b\}$. This system simulates the interplay between preys, x's, and predators, y's, in an environment with a variable amount of resources, a's. Preys breed when resources are available and are eaten by predators which also die – the last rule.

The transition from the state *Running* to itself, for the P system Π_1, which has cooperative and non-cooperative rules (r_1, r_4 and r_2, r_3, respectively), can be written as the following NuSMV specification:

```
state = running & next(state) = running &
(a - next(n1) - next(n2) < 1 ) &
(a - next(n1) - next(n2) < 1 | x - next(n2) - next(n3) < 1 ) &
(x - next(n2) - next(n3) < 1 | y - next(n3) - next(n4) < 1 ) &
(y - next(n3) - next(n4) < 1 ) &
(a - next(n1) - next(n2) >= 0) & (x - next(n2) - next(n3) >= 0) &
(y - next(n3) - next(n4) >= 0) &
next(a) = a - next(n1) - next(n2) + 2*next(n1) &
next(b) = b + next(n4) &
next(x) = x - next(n2) - next(n3) + 2*next(n2) &
next(y) = y - next(n3) - next(n4) + 2*next(n3) &
! (next(n1) = 0 & next(n2) = 0 & next(n3) = 0 & next(n4) = 0 ) &
! (next(a) > Max | next(b) > Max | next(x) > Max | next(y) > Max |
  next(n1) > Sup | next(n2) > Sup | next(n3) > Sup | next(n4) > Sup )
```

The first row describes the next state, i.e., this is a transition to the *Running* state. The next four lines show that no rule can be further applied, e.g., for the first rule all the a's have been consumed (`a - next(n1) - next(n2) < 1`). For the second rule, $r_2 : ax \to x^2$, the condition (`a - next(n1) - next(n2) < 1  | x - next(n2) - next(n3) < 1`) shows that all the a's or all the x's objects have been consumed. The next lines ensure that the rules applied in one step can not consume more objects then the available, e.g. `a - next(n1) - next(n2) >= 0`. Further, the *next* values for all the objects are computed. They are followed by the conditions which distinguish between destination states, more details can be found in [14].

When a specification is false, a counterexample is given, i.e., a trace of the FSM that falsifies the property. Consider for simplicity the initial multiset $w_1 = a^4 x^4 y^2$, $Sup = 5$, $Max = 8$ and the specification `G !((n3 > 0 &  X n4 > 0) &  F state = halt)` for Π_1. A test sequence checking that r_4 appears in the context of r_3 on a terminal computation starting with w_1 can be obtained. This is given by $a^4 x^4 y^2 \implies a^4 x^4 y^4 \implies b^4 x^8$ and the rules applied are r_1^2, r_2^2, r_3^2 in the first computation step and r_2^4, r_4^4 at the second step.

In the following we will present an excerpt of a counterexample received from NuSMV, for the P system Π_1 and the previous LTL specification, edited for brevity:

```
-- specification  G !((n3 > 0 &  X n4 > 0) &  F state = halt)  is false
-- as demonstrated by the following execution sequence
```

```
-> State: 20.1 <-        -> State: 20.2 <-          n1 = 0
  a = 4                    y = 4                     n2 = 4
  b = 0                    n1 = 2                    n3 = 0
  x = 4                    n2 = 2                    n4 = 4
  y = 2                    n3 = 2                 -- Loop starts here
  n1 = 0                 -> State: 20.3 <-          -> State: 20.4 <-
  n2 = 0                    a = 0                    n2 = 0
  n3 = 0                    b = 4                    n4 = 0
  n4 = 0                    x = 8                    state = halt
  state = running          y = 0
```

The values of all variables are listed only once, for the first configuration of the counterexample. Then, at the following steps, only the modified variables are printed. Based on the counterexample received for the specification `G !((n3 > 0 &  X n4 > 0) &  F state = halt)`, the tool computes the entire configuration at each step and the applied rules. The test case corresponding to the use of rule r_4 in the context of r_3, is represented by the P system derivation: $a^4x^4y^2 \implies a^4x^4y^4 \implies b^4x^8$. The rules used were: first r_1^2, r_2^2, r_3^2, then r_2^4, r_4^4, as it can be seen from the following table, corresponding to the counterexample above:

State	a	b	x	y	n1	n2	n3	n4	state
20.1	4	0	4	2	0	0	0	0	running
20.2	4	0	4	4	2	2	2	0	running
20.3	0	4	8	0	0	4	0	4	running
20.4	0	4	8	0	0	0	0	0	halt

5.3. Transforming multi-membrane P systems into SMV

The transformation of multi-membrane P systems into SMV is similar to the one for one-membrane P systems. The differences are the following:

- If the P system contains $p > 1$ membranes, the SMV model will contain $k \times p$ variables for the occurrences of the objects in each membrane; labelled like the symbols from the alphabet V, $|V| = k$, with an additional index, representing the membrane.

- The variables n_i, $1 \leq i \leq |R_1| + \ldots + |R_m|$ will be used to represent the number of applications of each rule r_i, (we have considered that the rules from all membranes are labelled $r_1, \ldots, r_{|R_1|+\ldots+|R_m|}$).

We will illustrate these differences, compared to the one-membrane P system, by specifying in NuSMV the P system $\Pi_2 = (V, \mu, w_1, w_2, R_1, R_2)$, $V = \{s, a, b, c\}$, $\mu = [_1[_2]_2]_1$, $w_1 = s$, $w_2 = \lambda$, $R_1 = \{r_1 : s \rightarrow sa(b, in); r_2 : s \rightarrow ab; r_3 : b \rightarrow a; r_4 : a \rightarrow c\}$, $R_2 = \{r_5 : b \rightarrow bc, r_6 : b \rightarrow c\}$.

The SMV model has the variables: $s_1, a_1, b_1, c_1, s_2, a_2, b_2, c_2, state$, the constants Max, Sup and the differences from the previous model will be given by the communications between membranes. For example, the number of objects b in the inner membrane, labelled with b_2, will take into account: the number of b objects consumed in membrane 2 by applying rules r_5, r_6, the number of objects b produces by the rules r_5 in membrane 2 and r_1 in membrane 1. An excerpt, representing the self loop from the state *running* is the following (edited for brevity):

```
state = running & next(state) = running &
s1 - next(n1) - next(n2) = 0 & b1 - next(n3) = 0 & a1 - next(n4) = 0 &
b2 - next(n5) - next(n6) = 0 &
next(s1) = s1 - next(n1) - next(n2) + next(n1) &
next(a1) = a1 - next(n4) + next(n1) + next(n2) + next(n3) &
next(b1) = b1 - next(n3) + next(n2) &
next(c1) = c1 + next(n4) &
next(s2) = s2 &
next(a2) = a2 &
next(b2) = b2 - next(n5) - next(n6) + next(n1) + next(n5)&
next(c2) = c2 + next(n5) + next(n6) &
! (next(n1) = 0 & ... & next(n6) = 0 ) &
! (next(s1) > Max | ... | next(c1) > Max |
   next(s2) > Max | ... | next(c2) > Max |
   next(n1) > Sup | ... | next(n6) > Sup )
```

5.4. Transforming P systems with dissolving rules into SMV

Similarly to the previous section, this P system model, which has $p > 1$ membranes, will have $k \times p$ variables to represent the occurrences of the objects in each membrane, a number of variables n_i equal to the total number of rules and some special variables, to mark the membranes affected by dissolving rules.

For each membrane that can be dissolved we will consider a variable $dis_i \in \{0, 1\}$, showing whether the membrane is dissolved (1) or it is still alive (0). When the membrane is dissolved its objects are assimilated by the outer membrane. In the SMV transformation we have used the variables dis_i as flags, to correctly update the values of the variables counting the occurrences of objects in each membrane.

Consider the P system $\Pi_3 = (V, \mu, w_1, w_2, R_1, R_2)$, $V = \{a, b, c\}$, $\mu = [_1[_2]_2]_1$, $w_1 = b$, $w_2 = abc$, $R_1 = \{r_1 : b \to c; r_2 : c \to a\}$, $R_2 = \{r_3 : b \to ab; r_4 : b \to b\delta, r_5 : c \to cc\}$. The inner membrane, labelled 2, can be dissolved when the rule r_4 is applied. In the SMV model the variable dis_2 is updated by the instruction:

```
next(dis2) := case
    dis2 = 1 : 1;      -- if membrane is dissolved, it remains dissolved
    next(n4) >= 1 : 1; -- if rule r4 is applied, membrane 2 dissolves
    1 : 0;             -- otherwise, the membrane remains alive (0)
esac;
```

If the membrane is dissolved (`dis2=1`), then it remains dissolved. When rule r_4 is applied (`next(n4)>=1`) the membrane will dissolve (next value is 1). Otherwise

(1 means *true* in this case and shows the default option), the membrane will remain alive, the next value is 0 (not dissolved).

An excerpt from the SMV file, edited for brevity, is given below. To ensure that, only when a membrane is dissolved its content is moved to the outer membrane, the rules for updating the quantities in the outer membrane, e.g., `next(a1)`, have added an extra term, e.g., `(a2 + next(n3))*next(dis2)`, representing the same type of objects from the inner membrane, multiplied with the next value `dis2`, because this term is null when the membrane is alive and represents the number of `a` objects in the second membrane in when this one dissolves. On the other hand, the values from the inner membrane will be multiplied with the opposed value, `1-next(dis2)`. When membrane 2 dissolves, the number of objects in membrane 2 will become 0 because the factor `(1-next(dis2)` is 0. Otherwise, the factor is 1 and the value is computed as usual (subtracting the consumed objects and adding the produced ones).

```
state = running & next(state) = running &
b1 - next(n1) = 0 & c1 - next(n2) = 0 &
b2 - next(n3) - next(n4) = 0 & c2 - next(n5) = 0 &
next(a1) = a1 + next(n2) + (a2 + next(n3))*next(dis2) &
next(b1) = b1 - next(n1) + b2*next(dis2) &
next(c1) = c1 - next(n2) + next(n1) + (c2 + next(n5))*next(dis2)&
next(a2) = (a2 + next(n3))*(1-next(dis2)) &
next(b2) = (b2 - next(n3) - next(n4) + next(n3) + next(n4))*(1 - next(dis2)) &
next(c2) = (c2 - next(n5) + 2*next(n5))*(1-next(dis2)) &
! (next(n1) = 0 & ... & next(n5) = 0)&
! (next(a1) > Max | ... | next(c2) > Max |
   next(n1) > Sup | ... | next(n5) > Sup )|
```

5.5. Using the transformed model to verify different properties

The transformation of a P systems into a model accepted by a specific model-checker, NuSMV, was used to generate test cases. For this, LTL specifications were written, such as `G !(n_2 > 0 &  F(state = halt))`, having the purpose of obtaining a terminal coverage for rule r_2. If the LTL specification is false, the counterexample obtained is decoded: it represents a path in the SMV model, which corresponds to a (possible partial) computation in the P system. The union of all test cases will form the test suite.

If an LTL specification like `G !(n2 > 0 & F(state = halt))` is true this means that: (1) rule r_2 is never applied or (2) rule r_2 is applied, but the computation does not finish, i.e., the system does not reach the *halt* state. Verifying the simpler specification `G  !(n2 > 0)` and receiving from the model checker the response 'specification is true' reveals the fact that this rule is never applied. This is normally a fault in the model and could be obtained in situations like the following:

```
@mu = [ ]'1;              @mu = [ ]'1;
@ms(1) = a*10,x*10,y*5;   @ms(1) = a*10,x*10,y*5;
[a --> a,a]'1;            [a --> a,a]'1;
[a,x --> x,x]'1           [z,x --> x,x]'1
[x,y --> y,y]'1;          [x,y --> y,y]'1;
[y --> b]'1;              [y --> b]'1;
```

In the left column is given a correct specification in P-Lingua of the P system Π_1; on the right side the second rule has a typo (z instead of a). Both fragments are syntactically correct, so the parser will accept them both. On the other hand, the second P system has different computations and rule r_2 is never applied, fact revealed by the specification `G !(n2 > 0)`. Also, properties such as `G (a = 0 ->  X a = 0)`, which states that if a certain resource was consumed it will never be produced again, can be verified.

The automatic transformation to NuSMV allows verifications of different LTL or CTL specifications, that might be useful at designing a P system, that models a certain process. Even simple propositions like `G !(a > 100)` let us know if there exist or not a computation in which the number of objects a can reach a certain level. And this answer is obtained quickly, without simulating hundreds of computations to see if this ever happens.

6. Related work

Only a few approaches on model checking P systems have been proposed until now. Among them, decidability of model checking problems for P systems was analysed and a discussion regarding the use of SPIN model checker provided [7], for P systems without priority rules and membrane dissolving rules. An operational semantics using rewriting logics and model checking based on Maude was given in [1]. Regarding probabilistic model checking of P systems Romero-Campero et al. proposed in [22] a transformation into a probabilistic and symbolic model checker called PRISM.

Several testing strategies for P systems have been presented, that use: coverage criteria inspired from grammar testing [11], finite state based testing [12] and stream X-machine models [13]. An approach to automate the test generation for P systems using model checking is presented in [14] and further extended in this work.

7. Conclusions

This paper extends our previous work on model-checking based P system testing [14]. It integrates this approach with P-Lingua, a software framework for cell-like P systems [10]. Compared to the previous work, the current tool offers support for multi-membrane P systems. Also, we propose an approach for transforming P systems with dissolving rules into NuSMV. The transformed model can be used not only for test generation, but also for verifying system properties. For testing it is preferable to obtain shorter test cases, so the BMC option of NuSMV can be very useful at test generation.

Future work will focus on other types of P systems, employed in modelling ecosystems [2] as well as other biological and interdisciplinary applications [4], for which automatic test generation and model checking would be very useful. We will study testing and verification of probabilistic and stochastic P systems, integration with P-Lingua and possible use of a probabilistic model checker, e.g., PRISM, as suggested in [22].

Another research topic concerns the study of other model checkers and improvements made to the strategies presented, to face the *state explosion* problem, which appears when more complex models are verified.
